An Introduction To Microwave Radio

characteristics of microwave signals. An electromagnetic wave does not travel in a straight line: the wave spreads out as it propagates. Also, the individual waves that make up a radio signal do not travel at the same phase velocity. A French physicist, Augustin Fresnel, defined the propagation of a radio wave as a three-dimensional

An Introduction to Microwave Radio Link Design

The evolution of radio from what is now known as 0G, for early radio, through to 6G, for sixth generation cellular radio, is used to present modern microwave and RF engineering concepts. Two key themes unify the text: 1) how system-level decisions affect component, circuit and subsystem design; and 2) how the capabilities of technologies, components, and subsystems impact system design.

Defining Microwaves Microwaves are used in radar, radio transmission, cooking and other applications that have become essential in our modern society. Microwaves are electromagnetic waves[1] generally defined as lying within the frequency range of 100 MHz (3 m wavelength) to 300 GHz[2] (1 mm wavelength).[i] Above 30 GHz, because wavelengths are measured in mm, it is the convention to call them mmWaves.

Most often it is the dielectric constant ϵR that is most important in microwaves. For electromagnetic radiation, the permittivity of the medium that the wave is propagating in is equal to $\epsilon R \epsilon 0$. In a vacuum or in dry air, ϵR is equal to unity, and the signal travels at the speed of light.

In the 1950s, AT&T built a 10-channel microwave radio relay system in the United States that was capable of carrying 5,400 long-distance calls per channel, supporting a total of 54,000 simultaneous callers. The emergence of television provided another opportunity, as network broadcasting was relayed to local affiliates across the country.
