The properties of solid metals can be explained by the structure of metal atoms and the bonding between those atoms. Recall that most metals have one, two, or three valence electrons. When metal atoms combine chemically with atoms of other elements, they usually lose valence electrons. As a result, they become positively charged ions.

A polar bond is a covalent bond in which atoms share electrons unequally. The atom that pulls the electrons more strongly gain a slight negative charge, while the atom that is "weaker" gains a slight positive charge. On the other hand, a nonpolar bond is a covalent bond in which atoms share electrons equally.
